1. **app.py**: Main app code. Remember to remove the following code snippet from the end of this file, since it is added in wsgi.py.

```python
if __name__ == "__main__":
    app.run(debug=True)
```

2. **wsgi.py**

```python
from app import app

if __name__ == "__main__":
    app.run(debug=True)
```

3. **index.py**

```python
from wsgi import app
```

4. The repo MUST have a **requirements.txt** file which can be made using the following command in the venv (virtual environment):

```
pip freeze>requirements.txt
```

5. **vercel.json**

```json
{
    "version":2,
    "builds": [
        {
            "src":"./index.py",
            "use":"@vercel/python",
            "config":{"runtime":"python3.12"}
        }
    ],
    "routes":[
        {
            "src":"/(.*)",
            "dest":"/"
        }
    ]
}
```

Here, "version":2, and everything under "routes" is kind of mandatory. The details under "build" will change project-wise.

6. Then upload this to Vercel and select repo. Specify environment (.env) file (if any).
